## Abstract

Paraneoplastic polyarthrititis is an inflammatory arthritis, is usually seronegative, and has a temporal and pathophysiological relationship with an underlying malignancy. Although head and neck tumors may be a cause of paraneoplastic polyarthrititis, its association with tongue carcinoma has not been previously reported. We present the case of a 69-year-old man who was a former smoker and presented with polyarthrititis since 2 months in the wrists, proximal interphalangeal joints, knees, and elbows, with increased levels of acute-phase reactants; negativity for rheumatoid factor, anticitrullinated cyclic peptide antibody, and antinuclear antibody; and negative results for crystals and microorganisms in the synovial fluid. Cervical computed tomography and posterior rhinoscopy were performed, which detected an asymptomatic lesion on the base of the tongue, whose biopsy was compatible with nonkeratinizing squamous cell carcinoma. Polyarthrititis did not respond to glucocorticoids at medium doses (oral prednisone 20 mg/day) but progressively resolved after the initiation of antineoplastic therapy.

**Keywords:** Paraneoplastic polyarthrititis, paraneoplastic syndrome, tongue carcinoma, head and neck neoplasms

## Introduction

Paraneoplastic polyarthrititis (PP) or carcinomatous polyarthrititis is an inflammatory arthritis, is usually seronegative, and has a temporal and pathophysiological relationship with an underlying malignancy, which usually corresponds to solid tumors, and less frequently, to hematological neoplasms (1, 2). Although head and neck tumors may be a cause of PP (3, 4), its association with tongue carcinoma (TC) has not been reported. We present a case of PP as an initial manifestation of CL.

## Case Presentation

A 69-year-old man consulted for pain and swelling in the right wrist of sudden onset and 2 months of evolution, which extended to contralateral wrist, proximal interphalangeal (PIP) joints 2, 3, and 5 of the right hand, knees, and elbows and was associated with asthenia, hyporexia, and weight loss of 10 kg. His history included smoking (20 cigarettes/day) and alcohol consumption until 50 years of age, JAK2-negative essential polyglobulia, and prostatectomy at 68 years of age due to prostatic adenocarcinoma, with undetectable prostate-specific antigen (PSA) after the procedure. Examination revealed synovitis in the wrists, right PIP joints 2, 3, and 5 (Figure 1), and knees, with moderate effusion in the left knee. He presented palpable lymph nodes of 1-2 cm in diameter, which were mobile and did not indurate or cause pain in the left cervical and supraclavicular regions; no lesions were observed in the oral cavity. Laboratory tests showed hypochromic microcytic anemia; mild thrombocytosis; C-reactive protein level of 95 mg/L; erythrocyte sedimentation rate of 51 mm/h; PSA level of 0 ng/mL; negative results for rheumatoid factor (RF), anticitrullinated cyclic peptide antibody, and antinuclear antibody; and tumor markers levels (carcinoembryonic antigen, CA 19-9,  $\alpha$ -fetoprotein, and  $\beta$ 2-microglobulin) within normal ranges. Left knee arthrocentesis was performed, revealing inflammatory fluid leukocyte count of 46000/ $\mu$ L (91% neutrophils), without crystals and negative cultures. Oral prednisone was started (10 mg/day), but polyarthrititis was persistent. X-ray examination of the hands showed increased soft tissue in the wrists and absence of erosions. Given the suspicion of a paraneoplastic condition, thoracic-abdominal-pelvic computed tomography (CT) and colonoscopy were performed, but they did not detect alterations. However, cervical CT showed pathological mucous thickening of lingual tonsils and regional adenopathies (Figure 2). Posterior rhinoscopy showed an exophytic/papillomatous lesion on the tongue base and lingual aspect of the epiglottis, whose biopsy was

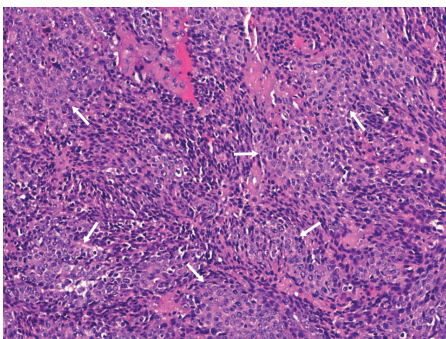

**Figure 1.** Swelling in the wrists and right proximal interphalangeal joints 2, 3 and 5 in relation to synovitis in these locations

**Figure 2.** Axial slice of cervical CT showing a pathological mucous thickening of lingual tonsils, well delimited and of homogeneous density (arrows)

**Figure 3.** Microscopic image of the tongue lesion corresponding to a non-keratinizing squamous cell carcinoma. A solid growth of squamous cells with nuclear atypia and mitosis (arrows) is observed. The cells are medium sized and do not present cytoplasmic keratinization (hematoloxilin-eosin 20X)

compatible with nonkeratinizing squamous cell carcinoma (Figure 3). The patient was diagnosed with PP secondary to TC. The dose of oral prednisone was increased to 20 mg/day,

without noticing changes. Subsequently, he received 2 cycles of local radiotherapy and 5 cycles of chemotherapy, with gradual resolution of polyarthrititis within the month of initiation of antineoplastic treatment. The patient has not presented new episodes of arthritis during a 6-month follow-up period.

Written informed consent was obtained from the patient.

## Discussion

Paraneoplastic syndrome (PS), including PP, is characterized by the following: 1) occurs during the course of a malignancy or precedes it, 2) symptoms do not arise from tumor invasion or compression, and 3) the clinical picture improves with the treatment of the underlying neoplasm (5). Caldwell and McCallum identified the key features of PP, which include a close temporal relationship arthritis/neoplasia (12 months), advanced age, asymmetric joint involvement, sudden onset, predominance of lower extremities respecting hands and wrists, absence of RF, rheumatoid nodules and radiographic erosions, absence of a family history of rheumatic disease, and nonspecific synovial histopathology (6), all of which were present in our case, except symmetry and hand involvement, which have also been described in some patients with PP (2). Its physiopathology is unknown, suggesting the participation of immunocomplexes and T lymphocytes with cross-reactivity against synovial antigens (1). PP responds poorly to treatment with non-steroidal anti-inflammatory drugs, glucocorticoids, and disease-modifying antirheumatic drugs, generally achieving its resolution with the treatment of the underlying neoplasm, although tumor recurrence is not usually associated with reappearance of arthritis (1, 2). PP has been reported as a manifestation of head and neck tumors, including laryngeal carcinoma (6), hypopharyngeal (4), and laryngopharyngeal (7), but not TC, and this neoplasm has been associated with other PSs, such as dermatomyositis, autoimmune retinopathy, subacute cerebellar degeneration, thrombophlebitis, and hypercalcemia (8-10). In our patient, the suspicion of PP led to the diagnosis of TC because it did not manifest direct symptoms of the tumor and was not accessible on physical examination; thus, it was detected in the complementary tests.

## Conclusion

Head and neck tumors, including TC, may be a cause of PP and may be the initial manifestation in some cases. However, these neoplasms

are not always evident on physical examination; hence, they must be considered, especially in patients with key characteristics of PP.
